## **Bellman equations**

$$V^{N} = (1 - \pi)\beta V^{E}(0) + \pi E_{\tau} \max\left\{y - m + \beta V^{N}, y - \tau + \beta V^{E}(0)\right\}$$

## **Bellman equations**

$$V^{N} = (1 - \pi)\beta V^{E}(0) + \pi E_{\tau} \max\left\{y - m + \beta V^{N}, y - \tau + \beta V^{E}(0)\right\}$$

$$V^{E}(n) = \phi_{n}V^{N} + (1 - \phi_{n})\beta V^{E}(n+1)$$

## **Bellman equations**

$$V^{N} = (1 - \pi)\beta V^{E}(0) + \pi E_{\tau} \max\left\{y - m + \beta V^{N}, y - \tau + \beta V^{E}(0)\right\}$$

$$V^{E}(n) = \phi_{n}V^{N} + (1 - \phi_{n})\beta V^{E}(n+1)$$

In particular,  $V^E(n) \leq V^N$  for all n

## Default

Investors choose to pay if

$$m \leq \tau + \beta \left[ V^N - V^E(0) \right]$$

making the lender's break-even condition

$$\pi\left(1-F\left(m-\beta\left[V^{N}-V^{E}(0)\right]\right)\right)m=R.$$

ъ

イロト 不同 とくほ とくほ とう

## Stationary distributions

$$\mu^{N} = \mu^{N}(1-\delta^{D}) + \sum_{n=0}^{+\infty} \mu^{E}(n)\phi_{n}$$
$$\mu^{E}(0) = \left[\mu^{N} + \sum_{n=0}^{+\infty} \mu^{E}(n)\phi_{n}\right]\delta^{D}$$
$$\mu^{E}(n) = \mu^{E}(n-1)(1-\phi_{n-1}) \text{ for all } n > 0$$

## Stationary distributions

$$\mu^{N} = \mu^{N}(1 - \delta^{D}) + \sum_{n=0}^{+\infty} \mu^{E}(n)\phi_{n}$$
  
$$\mu^{E}(0) = \left[\mu^{N} + \sum_{n=0}^{+\infty} \mu^{E}(n)\phi_{n}\right]\delta^{D}$$
  
$$\mu^{E}(n) = \mu^{E}(n-1)(1 - \phi_{n-1}) \text{ for all } n > 0$$

#### Lemma

A stationary equilibrium with  $\mu^N > 0$  exists only if

$$\sum_{n=0}^{+\infty} \prod_{s=0}^{n} (1-\phi_n) < +\infty.$$

◆□▶ ◆□▶ ★ □▶ ★ □▶ → □ → つく⊙

## Existence

## Proposition

A stationary equilibrium with strictly positive investment exists if and only if

1. 
$$\sum_{n=0}^{+\infty} \prod_{s=0}^{n} (1-\phi_n) < +\infty$$
,

2. A solution *m* ≤ *y* exists to the lender's break-even condition.

э

## **Optimal Exclusion**

Consider a social planner who designs the exclusion policy to maximize stationary welfare:

$$\mu^{N}V^{N} + \sum_{s=0}^{+\infty} \mu^{E}(s)V^{E}(s)$$

イロト イポト イヨト イヨト

# **Optimal Exclusion**

Consider a social planner who designs the exclusion policy to maximize stationary welfare:

$$\mu^{\mathsf{N}}\mathsf{V}^{\mathsf{N}} + \sum_{s=0}^{+\infty} \mu^{\mathsf{E}}(s) \mathsf{V}^{\mathsf{E}}(s)$$

### Proposition

In any stationary equilibrium that maximizes average welfare, the forgiveness policy must be such that for some  $s^*$ ,

1. 
$$\phi_s = 0$$
 for all  $s < s^*$ ;  
2.  $\phi_{s^*} \in (0, 1]$ ;  
3.  $\phi_{s^*+1} = 1$  and  $\phi_s \in [0, 1]$  for all  $s > s^* + 1$ 

1.

イロト イポト イヨト イヨト 二日

# Step 1: Maximize the welfare of the excluded

- Given V<sup>E</sup>(0), what policy maximizes the welfare of the excluded?
- Knowing  $V^E(0)$  pins down *m*,  $V^N$ , and  $\delta^D$
- Conditional on  $V^E(0)$  assume the planner maximizes

$$rac{\sum_{s=0}^{+\infty} \mu^{E}(s) V^{E}(s)}{\sum_{s=0}^{+\infty} \mu^{E}(s)}$$

subject to:

$$V^{E}(0) = \phi_{0} V^{N} + (1 - \phi_{0})\phi_{1}\beta V^{N} + (1 - \phi_{0})(1 - \phi_{1})\phi_{2}\beta^{2} V^{N} + \dots$$

That's best done by front-loading punishment (we show)

▲ □ ▶ ▲ □ ▶ ▲ □ ▶ □ □ ● ○ ○ ○

## Step 2: Maximize the number of transactions

Lemma

$$\mu^{N} = \frac{1}{1 + \frac{\delta^{D}}{1 - \delta^{D}}(1 + \zeta)}$$

where  $\zeta$  is negatively related to the welfare of the excluded

Monnet Quintin Optimal Exclusion

|▲■ ▶ ▲ 臣 ▶ ▲ 臣 ▶ □ 臣 □ • の Q ()>

## Step 2: Maximize the number of transactions

Lemma

$$\mu^{N} = \frac{1}{1 + \frac{\delta^{D}}{1 - \delta^{D}}(1 + \zeta)}$$

where  $\zeta$  is negatively related to the welfare of the excluded

# Maximizing the welfare of the excluded also maximizes the volume of transactions!

## Proposition

When default costs are homogenous at given value  $\tau$ , the optimal exclusion discount solves

$$\kappa = max\left(\pi^2(y-\tau) - \frac{1}{\beta}(R-\tau\pi), 0\right).$$

In particular, exclusion length falls with investor patience ( $\beta$ ), project size (y), project quality ( $\pi$ ), and with the direct punishment ( $\tau$ ) associated with default.

イロト イポト イヨト イヨト 二日

## Exclusion length with strategic default

# Assume that ex-post default costs are low at $\tau_L = \tau - \epsilon$ or high at $\tau_H = \tau + \epsilon$

<ロト < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 < つ < ○</p>

# Exclusion length with strategic default

Assume that ex-post default costs are low at  $\tau_L = \tau - \epsilon$  or high at  $\tau_H = \tau + \epsilon$ 

## Proposition

A mean-preserving spread in default costs raises exclusion length for  $\epsilon$  small enough but must eventually drives exclusion length to zero as  $\epsilon$  becomes large

## Extensions

- 1. Risk-averse investors
- 2. Exogenous punishment while excluded
- 3. Exogenous exit
- 4. Observable income
- 5. Non-stationary forgiveness policies
